Abstract. We review the history and various approaches to the derivation of Stirling's series. We use a different procedure, based on the asymptotic analysis of the difference equation $\Gamma(z+1) = z\Gamma(z)$. The method reproduces Stirling's series very easily and can be applied to analyze more complicated difference equations.

Keywords: Stirling's series, gamma function, difference equations, asymptotic analysis

MSC 2000 classification: primary 33B15, secondary 41A60

Introduction

The most widely known and used result in asymptotics is probably *Stirling's formula*,

$$n! \sim \sqrt{2\pi n} n^n e^{-n}, \quad n \rightarrow \infty \quad (1)$$

named after James Stirling (May 1692 – 5 Dec. 1770). The formula provides an extremely accurate approximation of the factorial numbers for large values of n . The asymptotic formula (1), for which Stirling is best known, appeared as Example 2 to Proposition 28 in his most important work, *Methodus Differentialis*, published in 1730 [41]. In it, he asserted that $\log(n!)$ is approximated by “three or four terms” of the series

$$\begin{aligned} \left(n + \frac{1}{2}\right) \log \left(n + \frac{1}{2}\right) - a \left(n + \frac{1}{2}\right) + \frac{1}{2} \log(2\pi) \\ - \frac{a}{24 \left(n + \frac{1}{2}\right)} + \frac{7a}{2880 \left(n + \frac{1}{2}\right)^3} - \dots, \quad (2) \end{aligned}$$

where \log means the base-10 logarithm and $a = [\ln(10)]^{-1}$ (see [40]).

In 1730 Stirling wrote to Abraham De Moivre (26 May 1667 – 27 Nov. 1754) pointing out some errors that he had made in a table of logarithms of factorials in his book and also telling him about (2). After seeing Stirling's results, De Moivre derived the formula

$$\ln[(n-1)!] \sim \left(n - \frac{1}{2}\right) \ln(n) - n + \frac{1}{2} \ln(2\pi) + \sum_{k \geq 1} \frac{B_{2k}}{2k(2k-1)n^{2k-1}}, \quad (3)$$

which he published in his *Miscellaneis Analyticis Supplementum* a few months later. Equation (3) is called *Stirling's series* and the numbers B_k are called the *Bernoulli numbers*, and are defined by

$$B_0 = 1, \quad \sum_{j=0}^k \binom{k+1}{j} B_j = 0, \quad k \geq 1. \quad (4)$$

Clearly Stirling and De Moivre regularly corresponded around this time, for in September 1730 Stirling related the new results of De Moivre in a letter to Gabriel Cramer.

In 1729 Leonhard Euler (15 April 1707 – 18 Sept. 1783) proposed a generalization of the factorial function from natural numbers to positive real numbers [11]. It is called the *gamma function*, $\Gamma(z)$, which he defined as

$$\Gamma(z) = \lim_{n \rightarrow \infty} \frac{n! n^z}{z(z+1) \cdots (z+n)}, \quad (5)$$

and it is related to the factorial numbers by

$$\Gamma(n+1) = n!, \quad n = 0, 1, 2, \dots$$

From Euler's definition (5), we immediately obtain the fundamental relation

$$\Gamma(z+1) = z\Gamma(z) \quad (6)$$

and the value $\Gamma(1) = 1$. In fact, the gamma function is completely characterized by the *Bohr-Mollerup theorem* [8]:

1 Theorem. *The gamma function is the only function $\Gamma : (0, \infty) \rightarrow (0, \infty)$ which satisfies*

- (i) $\Gamma(1) = 1$
- (ii) $\Gamma(x+1) = x\Gamma(x)$
- (iii) $\ln[\Gamma(x)]$ is convex for all $x \in (0, \infty)$.

PROOF. See [4] and [30]. \square

Another complex-analytic characterization is due to Wielandt [43]:

2 Theorem. *The gamma function is the only holomorphic function in the right half plane \mathbb{A} satisfying*

- (i) $\Gamma(1) = 1$

(ii) $\Gamma(z+1) = z\Gamma(z)$ for all $z \in \mathbb{A}$

(iii) $\Gamma(z)$ is bounded in the strip $1 \leq \operatorname{Re}(z) < 2$

PROOF. See [35].

QED

In terms of $\Gamma(z)$, we can re-write (1) as

$$\ln[\Gamma(z)] \sim \mathcal{P}(z), \quad z \rightarrow \infty \quad (7)$$

with

$$\mathcal{P}(z) = z \ln(z) - z - \frac{1}{2} \ln(z) + \frac{1}{2} \ln(2\pi) \quad (8)$$

and (3) in the form

$$\ln[\Gamma(z)] \sim \mathcal{P}(z) + R_N(z), \quad z \rightarrow \infty \quad (9)$$

where $R_0(z) = 0$ and

$$R_N(z) = \sum_{k=1}^N \frac{B_{2k}}{2k(2k-1)z^{2k-1}}, \quad N \geq 1. \quad (10)$$

Estimations of the remainder $\ln[\Gamma(z)] - \mathcal{P}(z) - R_N(z)$ were computed in [38].

1 Previous results

Over the years, there have been **many** different approaches to the derivation of (7) and (9), including:

- (i) Aissen [2] studied the sequence $V_n = \frac{n^n e^{-n}}{n!}$. Using his lemma

3 Lemma. *If*

$$\frac{y_{n+1}}{y_n} = 1 + \frac{\alpha}{n} + O(n^{-2})$$

and $y_n \neq 0$ for all n , then $y_n \sim Cn^\alpha$, $n \rightarrow \infty$ for some non-zero constant C .

he showed that $n! \sim C\sqrt{\pi n}n^n e^{-n}$.

- (ii) Bender & Orszag [5], Bleistein & Handelsman [6], Diaconis & Freedman [13], Dingle [14], Olver [33] and Wong [45] applied Laplace's method to the *Euler integral of the second kind*

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt, \quad \operatorname{Re}(z) > 0. \quad (11)$$

(iii) Bender & Orszag [5] and Temme [39] used *Hankel's contour integral* [1]

$$\frac{1}{\Gamma(z)} = \frac{1}{2\pi i} \int_{-\infty}^{(0+)} t^{-z} e^t dt$$

and the method of steepest descent.

(iv) Bleistein & Handelsman [6], Lebedev [25], Sasvári [37] and Temme [39] used *Binet's first formula*

$$\ln[\Gamma(z)] = \mathcal{P}(z) + \int_0^{\infty} \frac{1}{t} \left(\frac{1}{2} - \frac{1}{t} + \frac{1}{e^t - 1} \right) e^{-tz} dt, \quad \operatorname{Re}(z) > 0$$

and

$$\frac{1}{t} \left(\frac{1}{2} - \frac{1}{t} + \frac{1}{e^t - 1} \right) = \sum_{k \geq 1} \frac{B_{2k}}{(2k)!} t^{2k-2}, \quad |t| < 2\pi.$$

(v) Blyth & Pathak [7] and Khan [23] used probabilistic arguments, applying the Central Limit Theorem and the limit theorem for moment generating functions to Gamma and Poisson random variables.

(vi) Coleman [9] defined

$$c_n = \left(n + \frac{1}{2} \right) \ln(n) - n + 1 - \ln(n!),$$

and showed that $c_n \rightarrow 1 - \frac{1}{2} \ln(2\pi)$ as $n \rightarrow \infty$. A similar result was proved by Aissen [2], using the concavity of $\ln(x)$.

(vii) Dingle [14] used *Weierstrass' infinite product*

$$\frac{1}{\Gamma(z)} = z e^{\gamma z} \prod_{n=1}^{\infty} \left[\left(1 + \frac{z}{n} \right) e^{-\frac{z}{n}} \right],$$

(where γ is *Euler's constant*) and Mellin transforms.

(viii) Feller [17], [18] proved the identity

$$\ln(n!) - \frac{1}{2} \ln(n) = I(n) - I\left(\frac{1}{2}\right) + \sum_{k=1}^{n-1} (a_k - b_k) + a_n, \quad (12)$$

where

$$I(n) = \int_0^n \ln(t) dt, \quad a_k = \int_{k-\frac{1}{2}}^k \ln\left(\frac{k}{t}\right) dt, \quad b_k = \int_k^{k+\frac{1}{2}} \ln\left(\frac{t}{k}\right) dt$$

and showed that

$$\sum_{k=1}^{\infty} (a_k - b_k) - I\left(\frac{1}{2}\right) = \frac{1}{2} \ln(2\pi).$$

There is a mistake in his Equation (2.4), where he states that

$$\ln(n!) - \frac{1}{2} \ln(n) + I(n) - I\left(\frac{1}{2}\right) = \sum_{k=1}^{n-1} (a_k - b_k) + a_n,$$

instead of (12).

(ix) Hayman [19] used the exponential generating function

$$e^z = \sum_{k=0}^{\infty} \frac{1}{k!} z^k$$

and his method for admissible functions.

(x) Hummel [20], established the inequalities

$$\frac{11}{12} < r_n + \frac{1}{2} \ln(2\pi) < 1, \quad n = 2, 3, \dots,$$

where

$$r_n = \ln\left(\frac{n!e^n}{\sqrt{2\pi n}n^n}\right).$$

Impens [21], [22], showed that for $x > 0$

$$R_{2n}(x) < \ln[\Gamma(x)] - \mathcal{P}(x) < R_{2m+1}(x), \quad n, m \geq 0,$$

where $R_n(x)$ was defined in (10). Maria [26] showed that

$$\left[12n + \frac{3}{2(2n+1)}\right]^{-1} < r_n, \quad n = 1, 2, \dots$$

Mermin [28] proved the identity

$$e^{r_n} = \prod_{k=n}^{\infty} e^{-1} \left(1 + \frac{1}{k}\right)^{k+\frac{1}{2}},$$

which he used to show that $r_n \sim R_3(n)$. Michel [29], proved the inequality

$$\left| e^{r_n} - 1 - \frac{1}{12n} - \frac{1}{288n^2} \right| \leq \frac{1}{360n^3} + \frac{1}{108n^4}, \quad n = 3, 4, \dots$$

Nanjundiah [32], showed that

$$R_2(n) < r_n < R_1(n) = 1, 2, \dots$$

Robbins [36], established the double inequality

$$\frac{1}{12n+1} < r_n < \frac{1}{12n}, \quad n = 1, 2, \dots$$

(xi) Marsaglia & Marsaglia [27] derived from (11) the asymptotic expansion

$$n! \sim n^{n+1} e^{-n} \sum_{k=1}^{\infty} b_k \left(\frac{2}{n}\right)^{\frac{k}{2}} \Gamma\left(\frac{k}{2}\right) k,$$

where the generating function $G(z) = \sum_{k \geq 0} b_k z^k$ is defined by

$$G(z) \exp[1 - G(z)] = \exp\left(-\frac{1}{2}z^2\right), \quad G'(0) = 1.$$

(xii) Namias [31] introduced the function $F(n) = \frac{\Gamma(n)}{\mathcal{P}(n)}$, with $\mathcal{P}(n)$ defined in (8). From *Legendre's duplication formula*

$$\Gamma(2n) = \frac{2^{2n-1}}{\sqrt{\pi}} \Gamma(n) \Gamma\left(n + \frac{1}{2}\right), \quad (13)$$

he derived a functional equation for $F(n)$

$$\frac{F(2n)}{F(n)F\left(n - \frac{1}{2}\right)} = \sqrt{e} \left(1 - \frac{1}{2n}\right)^n,$$

from which he obtained (9). He also considered the triplication case, using *Gauss' multiplication formula*

$$\Gamma(mz) = \left(\sqrt{2\pi}\right)^{1-m} m^{mz - \frac{1}{2}} \prod_{k=0}^{m-1} \Gamma\left(z + \frac{k}{m}\right), \quad m = 2, 3, \dots$$

with $m = 3$. His results where extended by Deeba & Rodriguez in [12].

(xiii) Olver [33] used Euler's definition (5)

$$\ln[\Gamma(z)] = -\ln(z) + \lim_{n \rightarrow \infty} z \ln(n) + \sum_{k=1}^n [\ln(k) - \ln(z+k)]$$

and the Euler-Maclaurin formula. A similar analysis was done by Knopp [24] and Wilf [44].

(xiv) Patin [34] used (11) and the Lebesgue Dominated Convergence Theorem.

(xv) Whittaker & Watson [42] used *Binet's second formula*

$$\ln[\Gamma(z)] = \mathcal{P}(z) + 2 \int_0^{\infty} \frac{\arctan\left(\frac{t}{z}\right)}{e^{2\pi t} - 1} dt, \quad \operatorname{Re}(z) > 0$$

and

$$\arctan(x) = x \sum_{k=0}^{\infty} \frac{(-1)^k}{2k+1} x^{2k}, \quad |x| \leq 1.$$

Thus, there have been a huge variety of approaches to Stirling's result, ranging from elementary to heavy-machinery methods. In an effort to join such illustrious company, we present still another direction for deriving (9).

Our starting point shall be the difference equation (6). A parallel approach was considered in [3]. For a different analysis of (6) using the method of controlling factors, see [5]. Extensions and other applications of the method used can be found in [10], [15] and [16].

2 Asymptotic analysis

2.1 Stirling's formula

We begin with a derivation of (7), to better illustrate how the method works. We assume that

$$\ln[\Gamma(z)] \sim f(z) + g(z), \quad z \rightarrow \infty \tag{14}$$

with

$$g = o(f), \quad z \rightarrow \infty. \tag{15}$$

Using (14) in (6), we have

$$f(z+1) - f(z) + g(z+1) - g(z) \sim \ln(z). \tag{16}$$

Expanding $f(z+1)$ and $g(z+1)$ in a Taylor series, we obtain

$$f'(z) + \frac{1}{2}f''(z) + g'(z) \sim \ln(z). \quad (17)$$

From (15) and (17) we get the system

$$f'(z) = \ln(z), \quad \frac{1}{2}f''(z) + g'(z) = 0$$

and thus,

$$f(z) = z \ln(z) - z, \quad g(z) = -\frac{1}{2} \ln(z) + C. \quad (18)$$

To find the constant C in (18), we replace $\Gamma(z) \sim e^{f(z)+g(z)}$ in (13) and obtain

$$e^{f(2z)+g(2z)} \sim \frac{2^{2z-1}}{\sqrt{\pi}} e^{f(z)+g(z)} e^{f(z+\frac{1}{2})+g(z+\frac{1}{2})},$$

or

$$e^{C-\frac{1}{2}} \left(1 + \frac{1}{2z}\right)^z \sim \sqrt{2\pi}, \quad z \rightarrow \infty,$$

from which we conclude that $C = \ln(\sqrt{2\pi})$.

Hence, we have shown that

$$\ln[\Gamma(z)] \sim z \ln(z) - z - \frac{1}{2} \ln(z) + \frac{1}{2} \ln(2\pi), \quad z \rightarrow \infty.$$

2.2 Stirling's series

To extend the result of the previous section, we now assume that

$$\ln[\Gamma(z)] \sim \sum_{k=0}^N f_k(z), \quad z \rightarrow \infty \quad (19)$$

with

$$f_{k+1} = o(f_k), \quad z \rightarrow \infty, \quad k = 0, 1, \dots, N-1. \quad (20)$$

Using (19) in (6) we have

$$\sum_{k=0}^N f_k(z+1) - f_k(z) \sim \ln(z), \quad z \rightarrow \infty. \quad (21)$$

Replacing the Taylor series

$$f_k(z+1) = \sum_{j \geq 0} \frac{1}{j!} \frac{d^j}{dz^j} f_k(z)$$

in (21), we have

$$\sum_{k=0}^N \sum_{j \geq 1} \frac{1}{j!} \frac{d^j}{dz^j} f_k(z) \sim \ln(z), \quad z \rightarrow \infty. \quad (22)$$

From (20), we obtain the system of ODEs

$$\frac{d}{dz} f_0 = \ln(z)$$

and

$$\sum_{j=0}^{k-1} \frac{1}{(k+1-j)!} \frac{d^{k+1-j}}{dz^{k+1-j}} f_j(z) + \frac{d}{dz} f_k = 0, \quad k \geq 1,$$

which imply

$$f_0(z) = z \ln(z) - z \quad (23)$$

and

$$f_k(z) = - \sum_{j=1}^k \frac{1}{(j+1)!} \frac{d^j}{dz^j} f_{k-j}(z), \quad k \geq 1, \quad (24)$$

where we have omitted (for the time being) any constant of integration. To find the functions $f_k(z)$, we set

$$f_k(z) = a_k \frac{d^k}{dz^k} f_0(z) \quad (25)$$

in (24) and get $a_0 = 1$ and

$$a_k \frac{d^k}{dz^k} f_0(z) = - \sum_{j=1}^k \frac{1}{(j+1)!} \frac{d^j}{dz^j} \frac{d^{k-j}}{dz^{k-j}} f_0(z), \quad k \geq 1,$$

which gives

$$a_0 = 1, \quad a_k = - \sum_{j=1}^k \frac{1}{(j+1)!} a_{k-j}, \quad k \geq 1,$$

or

$$a_0 = 1, \quad \sum_{j=0}^k \frac{1}{(k+1-j)!} a_j = 0, \quad k \geq 1. \quad (26)$$

Multiplying both sides by $(k+1)!$, we can write (26) as

$$a_0 = 1, \quad \sum_{j=0}^k \frac{(k+1)!}{(k+1-j)! j!} a_j = 0, \quad k \geq 1,$$

or

$$a_0 = 1, \quad \sum_{j=0}^k \binom{k+1}{j} j! a_j = 0, \quad k \geq 1. \quad (27)$$

Comparing (4) and (27) we conclude that

$$a_k = \frac{B_k}{k!}, \quad k \geq 0. \quad (28)$$

Thus, from (23), (25) and (28) we have

$$f_k(z) = \frac{B_k}{k!} \frac{d^k}{dz^k} [z \ln(z) - z], \quad k \geq 0,$$

from which we obtain

$$f_1(z) = -\frac{1}{2} \ln(z) \quad (29)$$

and

$$f_k(z) = \frac{B_k}{k!} (-1)^k \frac{(k-1)!}{z^{k-1}} = \frac{(-1)^k B_k}{k(k+1) z^{k-1}}, \quad k \geq 2.$$

Since $B_{2k+1} = 0$ for all $k \geq 1$, we need to consider even values of k only,

$$f_{2k}(z) = \frac{B_{2k}}{2k(2k+1) z^{2k-1}}, \quad k \geq 1. \quad (30)$$

So far, we haven't included any constant of integration in our calculations. We could add a constant to one of the functions $f_k(z)$, let's say to $f_1(z)$, and proceed as in Section 2.1 to find it. Doing this, we would obtain from (23), (29) and (30) that

$$\sum_{k=0}^N f_k(z) = \mathcal{P}(z) + R_N(z)$$

where $\mathcal{P}(z)$, $R_N(z)$ were defined in (8) and (10) respectively.

Another possibility, would be to assume no previous knowledge of $\Gamma(z)$, except for the difference equation $\Gamma(z+1) = z\Gamma(z)$ and the value at 1, $\Gamma(1) = 1$. In doing so, (19) would imply the initial conditions $f_k(1) = 0$, for all $k \geq 0$. Hence, we would have

$$\begin{aligned} f_0(z) &= z \ln(z) - z + 1, & f_1(z) &= -\frac{1}{2} \ln(z) \\ f_{2k}(z) &= \frac{B_{2k}}{2k(2k+1) z^{2k-1}} - \frac{B_{2k}}{2k(2k+1)}, & k &\geq 1 \end{aligned}$$

and therefore

$$\ln [\Gamma(z)] \sim z \ln(z) - z - \frac{1}{2} \ln(z) + C_N + R_N(z), \quad (31)$$

with

$$C_N = 1 - \sum_{k=1}^N \frac{B_{2k}}{2k(2k+1)}. \quad (32)$$

Computing the first few C_N , we would get

$$\begin{aligned} C_1 &\simeq .91667, & C_2 &\simeq .91944, & C_3 &\simeq .91865, & C_4 &\simeq .91925, & C_5 &\simeq .91840, \\ C_6 &\simeq .92032, & C_7 &\simeq .91391, & C_8 &\simeq .94346, & C_9 &\simeq .76382, & C_{10} &\simeq 2.1562, \end{aligned}$$

and increasingly greater numbers (in absolute value). We would conclude that, before the sum starts diverging, the C_N seem to be approaching a value close to .918. Given our previous discussion of Stirling's formula, it is not surprising to find that $\frac{1}{2} \ln(2\pi) \simeq .91894$.

3 Conclusion

We have presented the history and previous approaches to the proof of Stirling's series (9). We have used a different procedure, based on the asymptotic analysis of the difference equation (6). The method reproduces (9) very easily and can be extended to use in more complicated difference equations.

Bender and Orszag observed in [5, Page 227] that

without further information the constant $\frac{1}{2} \ln(2\pi)$ cannot be determined. The difference equation that we have solved is linear and homogeneous, so any arbitrary multiple of a solution is still a solution.

While agreeing with them completely, we have shown that by imposing the additional condition $\Gamma(1) = 1$ one can find an approximation to the value of $\frac{1}{2} \ln(2\pi)$, without any other assumptions. Thus, local behavior at $z = 1$ and asymptotic behavior as $z \rightarrow \infty$ can be combined fruitfully.
